ABSTRACT

In this paper the quadratic programming problem with linear constraints containing absolute values (QPPLCAV) is considered. Hessian matrix is presumed to be positive definite. The problem is transformed to the larger problem with double number of variables with the same number of linear constraints without absolute values and with additional nonnegativity conditions (one inequality containing n absolute values could be 'directly' substituted by the system of 2n inequalities without absolute values). This problem may have several solutions. The relations between the original and the transformed problems are studied. In order to obtain stable approximations to the normal solution the transformed problem corresponding to the unique solution of the original problem a regularization technique is proposed. A numerical example is given.

Keywords: convex quadratic programming, portfolio optimization, linear constraints with absolute values, normal solution, regularization, stabilization

1. INTRODUCTION

Quadratic programming (QP) is the simplest nonlinear programming problem. An extensive research in this area starts with the pioneering work of [12]. In the paper [3] a comprehensive summary of quadratic programming bibliography (including items corresponding to electrotechnics and informatics, e.g., digital filter design or using Neural Networks to solve LP and QP problems) have been published, and quadratic programming codes have been listed at [4]. Authors refer to H. Mittelmann’s QP solvers site [14]. The numerical optimization including QP can be found, e.g., in books [2, 13]. A repository of convex quadratic programming problems is introduced in [13]. A survey on methods for solving the general quadratic programming problem is presented in [16]. There are numerous algorithms for the convex QP, see, e.g.,[2, 5–8, 10, 11, 18, 21, 23–26]. The comparison of five QP algorithms is given in [19].

Usually, QP problems with linear equality and inequality constraints are considered. In [1] optimal solutions to quadratic programs with quadratic constraints and inequality constraints expressed by means of $l_p$-norms are studied. We have not found papers dealing with linear constraints containing absolute values.

This paper is organized as follows. In Section 2 a brief motivation is given. In Section 3 the quadratic programming problem with linear constraints containing absolute values of variables (QPPLCAV) is introduced. Section 4 contains auxiliary theoretical results necessary to prove the main results. In Section 5 we propose a stable method for solving QPPLCAV. We transform the QPPLCAV to the QP problem with linear constraints without absolute values at a cost of doubling the number of variables, adding only nonnegativity constraints. To stabilize the solution of the transformed problem we introduce a regularization method. A numerical example is given in Section 6.

2. MOTIVATION

Consider a system of traded pairs $(\alpha_1, \beta_1), (\alpha_2, \beta_2), \ldots, (\alpha_m, \beta_m)$, where $m$ is the number of feasible pairs, $n$ is the number of assets, $\alpha_k, \beta_k \in \{1, 2, \ldots, n\}$, and $\alpha_k \neq \beta_k$ for all $k = 1, m$, where symbol $1, m$ denotes all integer numbers from the interval $[1, m]$, i.e., $1, m = 1, \ldots, m$ ([20]).

Let the corresponding relative investments $v_1, v_2, \ldots, v_m$ in these pairs fulfil the constraint

$$\sum_{j=1}^{m} q_j |v_j| \leq 1,$$

where $q_j > 0$ is the margin requirement associated with the $j$-th pair.

Wealth fractions $w_1$ (where $\sum_{i=1}^{n} w_i = 1$) invested in particular assets are related to $v_k$ by equations

$$w_1 = 1 + \sum_{i=1}^{m} v_i - \sum_{j=1}^{m} v_j,$$

$$w_k = \sum_{i=k}^{m} v_i - \sum_{j=k}^{m} v_j, \text{ for } k = 2, \ldots, n,$$

where the first asset represents the deposit currency.

An optimization portfolio problem

$$\frac{1}{2} w^T \tilde{C} w \to \min, \text{ where } \tilde{A}_{in} w \leq \tilde{b}_n \text{ and } \tilde{A}_{eq} w = \tilde{b}_{eq}$$

(4)

can be transformed using

$$w = f + M v$$

to the corresponding QP problem with the linear inequality constraint (1) containing absolute values of variables.

3. PROBLEM FORMULATION

Above we have arrived to the problem of the form:

$$\min_{x \in \mathbb{R}^n} \frac{1}{2} x^T C x + c^T x$$

(5)
subject to \[ A_{eq}x = b_{eq}, \quad b_{eq} \in \mathbb{R}^m, \]
\[ A_{in}x \leq b_{in}, \quad b_{in} \in \mathbb{R}^f, \]
\[ \sum_{j=1}^{n} q_{ij} |x_j| \leq 1, \quad \text{where } q_{ij} > 0 \]

for all \( j = 1, n \), and \( C = C' > 0 \) is a symmetric positive definite matrix of order \( n \) (‘ denotes matrix transposition, \( > 0 \) stands for positive definitivity of a matrix).

Let us formulate a more general problem which we will denote \textsc{Qplca}:

\[
\begin{align*}
\text{minimize} & \quad \frac{1}{2} x' C x + c' x \\
\text{subject to} & \quad A x = b, \quad b \in \mathbb{R}^m, \\
& \quad \sum_{j=1}^{n} q_{ij} |x_j| + p_{ij} x_j \leq s_i, \quad \text{where } q_{ij} \geq 0
\end{align*}
\]

for all \( i = 1, k \), \( j = 1, n \), \( C = C' > 0 \), and \( c \in \mathbb{R}^n \), \( x = [x_1, x_2, \ldots, x_n]' \in \mathbb{R}^n \), and \( b \in \mathbb{R}^m \) are column vectors.

Further we will use vector notation for vectors of absolute values: \( |x| = [|x_1|, \ldots, |x_n|]' \). So we may rewrite the inequalities in (9) in a matrix form

\[
Q|x| + Px \leq s,
\]

where \( Q \) and \( P \) are matrices of the size \( n \times n \), and \( s \in \mathbb{R}^n \). All elements of matrix \( Q \) we consider nonnegative. Inequalities from (6) can be included in (9) using zero rows in matrix \( Q \). Zero rows of matrix \( P \) correspond to the inequalities containing only absolute values, corresponding right side values \( s_i \) we consider positive.

Inequalities in both problems (5)–(6) and (7)–(8) could be rewritten in form of linear inequalities without absolute values (one inequality containing absolute values could be ‘directly’ substituted by the system of \( 2^n \) inequalities without absolute values). But the number of such inequalities will rapidly increase for large \( n \) even if \( k – \) the number of inequalities – is small.

We will transform the problem \textsc{Qplca} to the \textsc{Qp} problem of order \( 2n \) with the same number of equalities and inequalities adding nonnegativity conditions.

**Remark 3.1.** If we allow the element \( q_{ij} \) to be negative, the inequality (9) may define a non-convex domain in \( \mathbb{R}^n \). For example, consider inequality

\[
Q|x| \leq s, \quad \text{with } Q = [1, -1], \quad x = [x_1, x_2], \quad s = [1],
\]
or simply in a component form

\[
|x_1| - |x_2| \leq 1.
\]

The solution to this inequality is a non-convex subset of \( \mathbb{R}^2 \), see Fig. 1.

4. THEORETICAL PRELIMINARIES

In this section we will formulate and prove some auxiliary results from the matrix theory.

**Lemma 4.1.** Let \( C \) be a symmetric positive definite matrix of order \( n \), with the eigenvector \( v \) corresponding to the eigenvalue \( \lambda \). Denote \( \hat{C} \) a block matrix of the form

\[
\hat{C} = \begin{bmatrix} C & -C \\ -C & C \end{bmatrix}.
\]

Then the matrix \( \hat{C} \) has an eigenvector \( [v', -v']' \) corresponding to the eigenvalue \( 2\lambda \). All eigenvectors of the matrix \( \hat{C} \) corresponding zero eigenvalues are of the form \( [w', w'] \), \( w \in \mathbb{R}^n \).

**Proof.** We only multiply matrix \( \hat{C} \) by vector \( [v', -v'] \) and we get:

\[
\begin{bmatrix} v' \\ -v' \end{bmatrix} = \begin{bmatrix} C & -C \\ -C & C \end{bmatrix} \begin{bmatrix} v' \\ -v' \end{bmatrix} = \begin{bmatrix} Cvv' + C'v' \\ C'v - Cv' \end{bmatrix} = 2 \begin{bmatrix} \lambda v \\ -\lambda v \end{bmatrix} = 2\lambda \begin{bmatrix} v' \\ -v' \end{bmatrix}.
\]

So the truth of the first part of claim is evident. Now, suppose that matrix \( \hat{C} \) has an eigenvector of the form \( [w'_1, w'_2] \), \( w'_1, w'_2 \in \mathbb{R}^n \), corresponding to the zero eigenvalue. Then we have

\[
\begin{bmatrix} \theta' \\ \theta' \end{bmatrix} = \hat{C} \begin{bmatrix} w'_1 \\ w'_2 \end{bmatrix} = \begin{bmatrix} C & -C \\ -C & C \end{bmatrix} \begin{bmatrix} w'_1 \\ w'_2 \end{bmatrix} = \begin{bmatrix} C(w'_1 - w'_2) \\ C(w'_1 + w'_2) \end{bmatrix}.
\]

So \( C(w'_2 - w'_1) = 0 \) what implies \( w'_2 = w'_1 \) because \( C \) is the positive definite matrix with kernel consisting of zero vector \( \theta_0 \) only. \( \Box \)

**Corollary 4.1.** Let \( C \) be a symmetric positive definite matrix of order \( n \). Denote \( \hat{C} \) a block matrix of the form (10).

Then matrix \( \hat{C} \) has \( n \) zero eigenvalues and \( n \) positive eigenvalues that are eigenvalues of matrix \( C \) multiplied by 2. All eigenvectors of \( \hat{C} \) corresponding to the positive eigenvalues may be written in the form \( [v', -v'] \), where \( v \in \mathbb{R}^n \) are corresponding eigenvectors of matrix \( C \).
Lemma 4.2. Let $\tilde{C}$ be a matrix of the form [10] with symmetric positive definite matrix $C$. Let

$$\tilde{C}_\alpha = \tilde{C} + \alpha I_{2n}, \quad \alpha > 0,$$

where $I_{2n}$ is the identity matrix of size $2n$. Then $\tilde{C}_\alpha$ is symmetric positive definite matrix with $n$ minimal eigenvalues equal to $\alpha$. 

Proof. From Corollary 4.2 it follows that $\tilde{C} = \sum_{i=1}^{2n} \mu_i v_i v_i'$, where vectors $v_i \in \mathbb{R}^n$, $i = 1, 2n$ generate an orthonormal basis of the space $\mathbb{R}^{2n}$, and $\mu_i$ are nonnegative eigenvalues of the matrix $\tilde{C}$. Therefore we have $I_{2n} = \sum_{i=1}^{2n} v_i v_i'$. So

$$\tilde{C}_\alpha = \tilde{C} + \alpha I_{2n} = \sum_{i=1}^{2n} \mu_i v_i v_i' + \alpha \sum_{i=1}^{2n} v_i v_i' = \sum_{i=1}^{2n} (\mu_i + \alpha) v_i v_i'.$$

$n$ eigenvalues of matrix $\tilde{C}$ are zero, say $\mu_i, i = 1, n$. Corresponding eigenvalues of matrix $\tilde{C}_\alpha$ are then equal $\mu_i + \alpha = \alpha, i = 1, n$.

Lemma 4.3. Let $\tilde{C}_\alpha$ be a matrix of the form

$$\tilde{C}_\alpha = \begin{bmatrix} C - C & \alpha I_{2n} I_{2n} \end{bmatrix}, \quad \alpha > 0,$$

where $C$ is a symmetric positive definite matrix of order $n$ with eigenvalues $\lambda_i > 0$ and corresponding eigenvectors $v_i \in \mathbb{R}^n$, $i = 1, n$, and $I_{2n}$ is the identity matrix of order $2n$. Let $\{w_i \in \mathbb{R}^n, i = 1, n\}$ be an arbitrary basis of $\mathbb{R}^n$. Then the matrix $\tilde{C}_\alpha$ has:

(i) $n$ eigenvectors of the form $\begin{bmatrix} v_i \\ -v_i \end{bmatrix}$ corresponding to the eigenvalues $2\lambda_i, i = 1, n$;

(ii) $n$ eigenvectors of the form $\begin{bmatrix} w_i \\ w_i \end{bmatrix}$ corresponding to the eigenvalues equal to $2\alpha, i = 1, n$.

Proof. (i) Direct substitution leads to

$$\tilde{C}_\alpha \begin{bmatrix} v_i \\ -v_i \end{bmatrix} = \begin{bmatrix} C - C & \alpha I_{2n} I_{2n} \end{bmatrix} \begin{bmatrix} v_i \\ -v_i \end{bmatrix} = 2\lambda_i \begin{bmatrix} v_i \\ -v_i \end{bmatrix}.$$

(ii) Similarly

$$\tilde{C}_\alpha \begin{bmatrix} w_i \\ w_i \end{bmatrix} = \begin{bmatrix} C - C & \alpha I_{2n} I_{2n} \end{bmatrix} \begin{bmatrix} w_i \\ w_i \end{bmatrix} = 2\alpha \begin{bmatrix} w_i \\ w_i \end{bmatrix}.$$
Remark 5.2. We will not add here the request $x^i = 0$ for every $i = 1, \ldots, n$. We will discuss this problem later.

We have obtained the transformed problem TQPPLC in the space $\mathbb{R}^{2n}$ with linear constraints without absolute values:

$$\begin{align*}
\text{minimize} & \quad \frac{1}{2} \left[ x^+ - x^- \right]' \left[ \begin{array}{cc} C & -C \\ -C & C \end{array} \right] \left[ x^+ - x^- \right] + \left[ c^+ - c^- \right]' \left[ \begin{array}{c} x^+ \\ x^- \end{array} \right] \\
\text{subject to} & \quad \left[ A - A^T \right] \left[ \begin{array}{c} x^+ \\ x^- \end{array} \right] = b, \quad b \in \mathbb{R}^n, \\
& \quad \left[ (Q + P) - (Q - P) \right] x^+ \leq s, \\
& \quad \text{where } s > 0, \quad Q \succeq 0, \quad n \times n, \\
& \quad \left[ x^+ - x^- \right] \geq 0_{2n}.
\end{align*}$$

(15)

Remark 5.3. According to the Corollary 4.1 Hessian matrix $\hat{C}$ of the problem TQPPLC is positive semidefinite, so the problem TQPPLC may have more than one solution.

5.2. Equivalence of the problems QPPLCAV and TQPPLC

Problems QPPLCAV and TQPPLC are not completely equivalent. The problem QPPLCAV has a unique solution, if its feasible set is nonempty. In such a case the problem TQPPLC may have several solutions. However, in this case there always exists the solution of the problem TQPPLC corresponding to the solution of the problem QPPLCAV.

Theorem 5.1.

(i) Any feasible solution $x$ of the problem QPPLCAV corresponds to the feasible solution of the problem TQPPLC of the form $[x^+, x^-]'$, where $x^+$ and $x^-$ are defined by (13), with the same value of the objective function.

(ii) For any feasible solution of the problem TQPPLC of the form $[x^+, x^-]'$ vector $x = x^+ - x^-$ is the feasible solution of the problem QPPLCAV with the same value of the objective function.

Proof. (i) Using substitution (13)–(15) we get the problem (15)–(16). Here for every $i = 1, \ldots, n$ one of the values $x^i$ or $x^i$ is zero.

(ii) Let $[x^+, x^-]'$, $x^+ \geq 0$, $x^- \geq 0$ be the feasible solution of TQPPLC. If $x^i > 0$, $x^i = 0$ for all $i = 1, \ldots, n$, then $x = x^+ - x^-$ is the feasible solution of the problem QPPLCAV with the same value of the objective function — it is sufficient to use relations (13)–(14) to show it. If $x^i > 0$, $x^i > 0$ for some $i$, using (14) is not correct: $|x^i - x^i| \neq x^i + x^i$. However in both cases we may use vector $\hat{x} = x^+ - x^-$ with

$$\begin{align*}
\hat{x}^i &= x^i - \min(x^+, x^-) \geq 0, \\
\hat{x}^i &= x^i - \min(x^+, x^-) \geq 0,
\end{align*}$$

where under min we understand component-wise minimum. It is clear that now $\hat{x}^i \cdot \hat{x}^i = 0$ for all $i = 1, \ldots, n$. Because $\min(x^i, x^i) \geq 0$, $\hat{x}^i \leq x^i$, hence $\hat{x}^i + \hat{x}^i \leq x^i + x^i$. We have

$$\begin{align*}
\hat{x}^i - \hat{x}^i &= [x^i - \min(x^i, x^i)] - [x^i - \min(x^i, x^i)] \\
&= x^i - x^i \\
\text{for all } i = 1, n, \text{ hence obviously the equalities}
\end{align*}$$

$$\begin{align*}
A\hat{x} &= A(x^+ - x^-) = A(x^+ - x^-) = b, \\
\frac{1}{2} \hat{x}' C \hat{x} + c' \hat{x} &= \frac{1}{2} (x^+ - x^-)' C (x^+ - x^-) + c'(x^+ - x^-),
\end{align*}$$

hold true.

So, the equality constraints in the problem QPPLCAV for the vector $\hat{x}$ are satisfied, and the values of the objective functions of TQPPLC for vector $[x^+, x^-]'$ and QPPLCAV for vector $\hat{x}$ are the same. Now let us consider the $i$-th row of the inequality

$$Q(\hat{x}^i + \hat{x}^-) + P(\hat{x}^i - \hat{x}^-) \leq s.$$ 

For $i = 1, \ldots, k$ we have

$$\begin{align*}
\sum_{j=1}^{n} q_{ij} (\hat{x}^j + \hat{x}^-) + \sum_{j=1}^{n} p_{ij} (\hat{x}^j - \hat{x}^-) & \geq 0, \\
\sum_{j=1}^{n} q_{ij} (\hat{x}^j + \hat{x}^-) + \sum_{j=1}^{n} p_{ij} (\hat{x}^j - \hat{x}^-) & \leq s_i.
\end{align*}$$

Because vector $[x^+, x^-]'$ is the feasible solution of the TQPPLC, we get

$$Q(\hat{x}^i + \hat{x}^-) + P(\hat{x}^i - \hat{x}^-) \leq s,$$

and vector $\hat{x}$ is a feasible solution of QPPLCAV. But

$$\hat{x} = \hat{x}^+ - \hat{x}^- = [x^+ - \min(x^+, x^-)] - [x^- - \min(x^+, x^-)]$$

$$= x^+ - x^- = x.$$

So the claim (ii) is proven. \hfill \Box

Definition 5.1. The solution $\hat{x}$ of the minimization problem which minimizes some stabilization functional $\Omega(x)$ on the set of all solutions to the minimization problem is called $\Omega$-normal solution of the problem, see [22]. The solution $[x^+, x^-]'$ defined above is the $\Omega$-normal solution of the problem TQPPLC for stabilization functionals

$$\begin{align*}
\Omega_1(x^+, x^-) &= \|x^+\|_1 + \|x^-\|_1, \\
\Omega_2(x^+, x^-) &= \|x^+\|_2^2 + \|x^-\|_2^2 - \|x^+ - x^-\|_2^2.
\end{align*}$$

(18) and (19)
Figs. 2 and 3 show normal solutions for both stabilization functionals. Lines $x_i^+ - x_i^- = c$ represent feasible solutions (it may be bounded) for the $i$-th component. Minimal values of stabilization functional we achieve on the halfaxis (at the point $[0, -c_1]$ resp. $[c_2, 0]$ for $c_1 < 0$ resp. for $c_2 > 0$). The normal solution will have at least one zero value for each pair of components $x_i^+$ and $x_i^-$. 

\begin{figure}[h]
\centering
\includegraphics[width=0.8\textwidth]{fig2.png}
\caption{Normal solutions for $\| \cdot \|_1$}
\end{figure}

\begin{figure}[h]
\centering
\includegraphics[width=0.8\textwidth]{fig3.png}
\caption{Normal solutions for $\| \cdot \|_2$}
\end{figure}

Lemma 5.1. The normal solution of the problem TQPPLC with non-empty feasibility set with respect to the stabilization functional $\Omega_1$ or $\Omega_2$ is unique.

Proof. If the feasibility set of the problem TQPPLC is non-empty, then it is convex. Let us consider two different normal solutions $\tilde{x}_1 = [x_1^+, x_1^-]$ and $\tilde{x}_2 = [x_2^+, x_2^-]$ with $\Omega_i(\tilde{x}_1) = \Omega_i(\tilde{x}_2) = \Omega^*$, $i = 1, 2$. Then $\tilde{x} = [\tilde{x}_1 + \tilde{x}_2]/2$ is the solution too, because the matrix $\tilde{C}$ is non-negative semidefinite. But

$$\Omega_i([\tilde{x}_1 + \tilde{x}_2]/2) < [\Omega_i(\tilde{x}_1) + \Omega_i(\tilde{x}_2)]/2 = \Omega^*,$$

$i = 1, 2$ if the vectors $\tilde{x}_1$ and $\tilde{x}_2$ are different. We get the contradiction, because both normal solutions should minimize the functional $\Omega_i$, $i = 1, 2$, on the set of solutions.

5.3. Stabilization of the solution of the TQPPLC problem

Using Theorem 5.1 first we may find some solution $[x^{+\prime}, x^{-\prime}]^T$ to the problem TQPPLC, and then we get the solution $x = x^+ - x^-$ to the original problem QPPLCAV corresponding to the normal solution of the problem TQPPLC. However, since Hessian matrix $\tilde{C}$ of the form (10) of the problem TQPPLC is only positive semidefinite, it may cause problems by the numerical solution of the problem. We would like to get a good enough approximation to the $\Omega^*$-normal solution of the problem TQPPLC.

Let us consider the problem TQPPLC with modified Hessian matrix. We arrive to the problem MTQPPLC if we use in (15) the matrix $\tilde{C}_\alpha$ of the form (11) instead of the matrix $\tilde{C}$, $\alpha > 0$. Let us denote the solution to the problem MTQPPLC by $[x_\alpha^+, x_\alpha^-]$, and the corresponding approximation of the solution to the original problem QPPLCAV by $x_\alpha = x_\alpha^+ - x_\alpha^-$. 

Theorem 5.2. Let $\tilde{x} \in \mathbb{R}^n$ be the solution of the problem QPPLCAV. Then

$$\tilde{x} = \lim_{\alpha \to 0^+} x_\alpha.$$

Remark 5.4. Here we suppose, that the feasible set of the problem QPPLCAV is not empty, and so it has a unique solution $\tilde{x} \in \mathbb{R}^n$. If the feasible set of the original problem is empty and the solution $\tilde{x}$ does not exist, the problem MTQPPLC with the same (empty) feasible set has no solution too.

Proof. Because the feasible set of the problem QPPLCAV is nonempty, the feasible sets of both problems TQPPLC and MTQPPLC are nonempty, too. So from Corollary 4.3 it follows that the problem MTQPPLC has a unique solution for any $\alpha > 0$.

The solution $\tilde{x} = x^+ - x^-$ corresponds to the normal solution $[x^{+\prime}, x^{-\prime}]^T$ to the problem TQPPLC with respect to the stabilization functional $\Omega_2$ defined by (19).

For any $\alpha > 0$ we have

$$\frac{1}{2} \left[ x_\alpha^\prime \right]^T \tilde{C} \left[ x_\alpha^\prime \right] + [\alpha', -\alpha'] \left[ x_\alpha^+ \right] + \alpha \left[ x_\alpha^- \right]^2 \leq \frac{1}{2} \left[ x^+ \right]^T \tilde{C} \left[ x^+ \right] + [\alpha', -\alpha'] \left[ x^+ \right] + \alpha \left[ x^- \right]^2$$

Comparing the first and the third parts of (20) we conclude, that $\| [x_\alpha^+ - x_\alpha^-] \|_2 \leq \| [x^+ - x^-] \|_2$, or $\Omega_2([x_\alpha^+ - x_\alpha^-]) \leq \Omega_2([x^+ - x^-])$. So, all solutions $[x_\alpha^+ - x_\alpha^-] \in \mathbb{R}^{2n}$ belong to the compact set defined as

$$\{ [x^+ - x^-] \in \mathbb{R}^{2n} | \Omega_2([x^+ - x^-]) \leq \Omega_2([x^+ - x^-]) \}.$$
\[ x_+^*, x_-^* \] = \lim_{k \to \infty} [x_{a_k}^+, x_{a_k}^-]. \] Using continuity of the matrix product, and taking \( a_k \to 0 \) in (20), we get
\[
\begin{align*}
\frac{1}{2} \left[ x_+ x_+^T \right] & \tilde{C} \left[ x_+ x_+^T \right] + \tilde{C} ^T \left[ x_+ x_+^T \right] \\
\frac{1}{2} \left[ x_- x_-^T \right] & \tilde{C} \left[ x_- x_-^T \right] + \tilde{C} ^T \left[ x_- x_-^T \right] \\
\end{align*}
\]
where \( \tilde{C} = [c', -c'] \), together with
\[
\Omega_2(x_+^*, x_-^*) \leq \Omega_2(x_+^*, x_-^*).
\]

Since vector \( [x_+^*, x_-^*] \) is the normal solution of the problem TQPPLC, we conclude, using Lemma [5.1] that \( [x_+^*, x_-^*] = [x_+^*, x_-^*] \). Since all convergent subsequences of the sequence \( [x_{a_k}^+, x_{a_k}^-] \) belonging to the compact in \( \mathbb{R}^{2n} \) have the same limit, the sequence \( [x_{a_k}^+, x_{a_k}^-] \) is convergent with the same limit. We may conclude that \( \lim_{a \to 0^+} x_a = x = \bar{x} \).

**Remark 5.5.** We can use in (15) the matrix \( \tilde{C}_\alpha \) of the form (12) instead of the matrix \( \tilde{C} \). Then we obtain the problem with positive definite matrix, too. This is another stabilization possibility, which is related with using the stabilization functional of the form (18).

**Remark 5.6.** Theorem [5.2] claims that regularized solution \( x_\alpha \) converges to the normal solution \( \bar{x} \) as \( \alpha \) tends to zero. However, it is not possible to write an upper bound for the discrepancy between these two solutions for the general problem.

Let us consider next example:

\[
\text{minimize } x' \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} \quad \text{ subject to } \quad \begin{bmatrix} x_1 \\ a_1 \end{bmatrix} + \begin{bmatrix} x_2 \\ a_2 \end{bmatrix} \geq \begin{bmatrix} 1 \\ 0 \end{bmatrix}, \quad x \geq 0,
\]

The set of feasible solutions is shown in Fig. 4. The segment \([a_2, \infty)\) of the \( x_2 \)-axis is the set of all solutions with the normal solution at the point \( x = [0, a_2] \).

![Fig. 4](image)

**Table 1** Regularized solutions and the distance between the regularized and the normal solution for \( a_1 = 0.3 \) and \( a_2 = 3 \)

| \( \alpha \)   | \( x_{\alpha,1} \) | \( x_{\alpha,2} \) | \( |\Delta x_{\alpha,1}| \) | \( |\Delta x_{\alpha,2}| \) |

**6. NUMERICAL EXAMPLE**

Let us consider a problem QPPLCA V with

\[
C = \begin{bmatrix} 4 & 3 & 2 & 1 \\
3 & 4 & 3 & 2 \\
2 & 3 & 4 & 3 \\
1 & 2 & 3 & 4 \end{bmatrix}, \quad e = \begin{bmatrix} 0 \\
0.01 \\
0 \\
-1 \end{bmatrix},
\]

with the linear inequalities containing absolute values

\[ |x_1| + 2|x_2| \leq 4, \quad 2|x_1| + 3|x_4| \leq 3, \]

and with equality constraints

\[ x_1 + x_2 + x_3 + x_4 = 1, \]

\[ 0.2x_1 + 0.3x_2 + 0.2x_3 + 0.4x_4 = 0.15. \]
We have first rewrite 2 constraints with absolute values into 8 constraints without absolute values. As a result we get the optimal solution of the original problem QPPLC – AV – x = [0.92, −0.84, 0.75, 0.17]T and the corresponding minimal value of the objective function f_{min} = 1.5333.

Next we have solved the problem TQPPLC directly, without regularization. Further we have solved the problem MTQPPLC for values α = 10^{-1}, 10^{-2}, \ldots, 10^{-14}.

Even for large value α = 0.1 obtained regularized approximation to the normal solution x_{0.1} = [0.87503, −0.75615, 0.75305, 0.12808]T is close to the solution x = [0.92, −0.84, 0.75, 0.17]T of the original problem. Tab. 2 shows the components of the regularized solutions and the corresponding functional values for different values of parameter α. In the first row the normal solution and its functional value is given, the second row corresponds to the numerical solution of the problem TQPPLC without regularization using MATLAB® function quadprog with zero components of the initial vector (the solution does not meet the first inequality constraint). Tab. 3 shows the differences between components of the normal solution and the regularized solutions, and the differences f_{a} = \tilde{f} between the corresponding functional values. Choosing α = 10^{-6} ÷ 10^{-5} seems to be reasonable giving the sufficient high precision.

7. CONCLUSIONS

Quadratic programming problem with linear constraints containing absolute values of variables may lead to very large number of inequalities. Direct solution of the transformed problem TQPPLC with double number of variables and adding nonnegativity constraints may lead and often leads to the correct solution. However, as it is clear from our example, it may be better to use regularized solution solving the regularized problem MTQPLC with small value α. If given data C, c, A, b, P, Q, and s are not exact, more sophisticated method for choosing the appropriate value of the parameter α should be considered.

**BIOGRAPHY**

Ján Buša was born on 30.6.1958. In 1982 he graduated (RNDr) with distinction at the department of Computational Physics of the Faculty of Numerical Mathematics and Cybernetics at Moscow State University in Russia. He defended his CSc in the field of applied mathematics in 1987: his thesis title was “Solving the Linear Systems with Inaccurate Given Data”. Since 1986 he is working as a teacher at the Department of Mathematics and Theoretical Informatics. His scientific research is focusing on applied mathematics and numerical methods.
