ABSTRACT

We introduce security protocols by analyzing and verifying their properties. We use spi-calculus, an extension of the π-calculus, that enables us to consider cryptographic issues in more details. In this work we represent the security protocol as a process and we use the behavioral equivalences for describing secrecy and authenticity properties. Our goal is to design the practical procedure for verification of security protocols.

Keywords: protocol, spi-calculus, secrecy, authenticity, π-calculus

1. INTRODUCTION

Cryptographic protocols are used today to provide security in various applications. Cryptographic protocols are rules for exchange of messages between participants, and rely on cryptographic algorithms like encryption and decryption. Experience has shown that even very simple protocols which seem secure may have subtle flaws, even if the underlying cryptographic algorithms are secure. An extension of the π-calculus, the spi-calculus [1], was proposed as a formal notation for describing and reasoning about cryptographic protocols.

The objective of our work is to find a practical method of modeling and verifying cryptographic protocols using spi-calculus and validate it on specific communicating protocols. We analyze cryptographic protocols and their security properties. By means of basic knowledge about process algebras we use spicalculus for specification of cryptographic protocols. We develop and evaluate common formal method for the verification of cryptographic protocols.

2. CALCULUS OF SECURITY PROTOCOL

A protocol \( P = C^* \cup C \), where clauses in \( C \) use symbols from \( \Sigma \), predicates from \( P^* \cup P \), and contain predicates from \( P^* \) only in the body. We can write \( c(M) \) to denote a process that sends the message \( M \) on channel \( c \) after which it executes the process \( P \). Then \( c(x)M \) denotes a process that is listening on the channel \( c \) and if it receives some message \( M \) on this channel then it will execute the process \( Q[M/x] \).

We may compose these two processes in parallel to get a bigger process, denoted as \( (\ v(M)) \cdot P \ | \ c(x) \cdot Q \). Now the two smaller processes may communicate on the channel \( c \) after which they will execute the process \( P \ | \ Q[M/x] \ [2] \). The cryptographic protocol is communicating protocol, which uses the cryptography to achieve security goals. Basic cryptographic algorithms are DES, RSA, and DSA, and may be vulnerable if key is too short.

2.1. Abstract Syntax of the Calculus

The abstract syntax of the spi-calculus [1] is divided into two parts, terms and processes.

\[
L, M, N ::= \begin{cases}
\, n & \text{Name} \\
\, (M, N) & \text{Pair} \\
\, 0 & \text{Zero} \\
\, \text{suc}(M) & \text{Successor} \\
\, x & \text{Variable} \\
\, \{M\}_N & \text{Shared key encryption} \\
\end{cases}
\]

\[
P, Q, R ::= \begin{cases}
\, M[N].P & \text{Output - process is ready to output on channel } m \\
\, M(x).P & \text{Input - process is ready to input from channel } m \\
\, P \ | \ Q & \text{Composition - behaves as process } P \text{ and } Q \text{ running in parallel} \\
\, !P & \text{Replication behaves as a finite number of copies of } P \text{ running in parallel} \\
\, [M \text{ is } N]P & \text{Match behaves as } P \text{ if the terms } M \text{ and } N \text{ are the same; otherwise it is stuck (it does nothing)} \\
\, 0 & \text{Nil process does nothing} \\
\, \text{let } (x, y) = M \text{ in } P & \text{Pair splitting processes} \\
\, \text{case } M \text{ of } 0 : P \text{ suc}(x) : Q & \text{Integer case behaves as } P \text{ if the term } M \text{ is 0, as } Q[N/x][L/y] \text{ if the term } M \text{ is the pair } (N, L) \\
\, \text{case } L \text{ of } \{x\}_N \text{ in } P & \text{Shared key decryption} \\
\end{cases}
\]

2.2. Semantic of the Calculus

Let \( fn(M) \) and \( fn(P) \) be a set of free names in term \( M \) and process \( P \). Let \( fV(M) \) and \( fV(P) \) be the set of free variables in term \( M \) and process \( P \). Closed processes are processes without any free variables. [3]
**Reaction relation**: $P \rightarrow Q$ means that there exists a reaction between subprocesses of $P$ such that the whole can step to process $Q$:

\[
\bar{m}(N).P \rightarrow m(x).Q \rightarrow P | Q[N/x]
\]

Interaction

Then we define the **reduction relation** $\triangleright$ on closed processes:

\[
\begin{align*}
&M \triangleright P | P \quad \text{Replication} \\
&M \triangleright P \text{ is } M | P \quad \text{Match} \\
&P | (Q | R) \triangleright (P | Q) | R \quad \text{Association} \\
&(\nu m)(\nu n)P \triangleright (\nu m)(\nu n)P \quad \text{Switch} \\
&(\nu n)0 \triangleright 0 \quad \text{Drop} \\
&(\nu n)(P | Q) \triangleright (P | (\nu n)Q \text{ if } n \notin fn(P) \quad \text{Extrusion}
\end{align*}
\]

**Structural equivalence** is a relation on closed processes that satisfies the following rules and equation:

\[
\begin{align*}
P &| 0 \equiv Nil \\
P &| Q \equiv Q | P \quad \text{Commitment} \\
P &| (Q | R) \equiv (P | Q) | R \quad \text{Association} \\
(\nu m)(\nu n)P &\equiv (\nu m)(\nu n)P \quad \text{Switch} \\
(\nu n)0 &\equiv 0 \quad \text{Drop} \\
(\nu n)(P | Q) &\equiv P | (\nu n)Q \quad \text{Extrusion}
\end{align*}
\]

**Reduction**

\[
\begin{align*}
P &\triangleright Q \quad \text{Reflection} \\
M &\equiv Q \quad \text{Symmetry} \\
M &\equiv P \quad \text{Transitivity}
\end{align*}
\]

\[
\begin{align*}
P &\equiv Q \quad P \equiv P' \quad P \equiv P'
\end{align*}
\]

\[
\begin{align*}
P &\equiv R \quad P | Q \equiv P' | Q \\
(\nu m)P &\equiv (\nu m)P'
\end{align*}
\]

With these rules we can complete reaction rules as follow:

\[
\begin{align*}
P &\equiv P' \rightarrow Q' \equiv Q \quad P \rightarrow P' \\
&\rightarrow Q \\
(\nu n)P &\rightarrow (\nu n)P'
\end{align*}
\]

Abadi and Gordon [1] use **testing equivalence** as the notion of equivalence. Two processes are testing equivalent, written $P \equiv Q$, if they are indistinguishable to any other process. For specification of testing equivalence [2] we first define bars. **Barbs** define a predicate describing the channels, where output process can communicate. A barb $\beta$ is an input or an output channel, where output channels are marked by a barb $\bar{m}$. $P$ exhibits barb $\bar{\beta}$, written $P \downarrow \bar{\beta}$, is defined:

\[
\begin{align*}
m(x).P \downarrow m \\
\bar{m}(M).P \downarrow \bar{m}
\end{align*}
\]

Barb Parametrization Barb Restriction Barb Structural

\[
\begin{align*}
P \downarrow \bar{\beta} &\quad P \downarrow \bar{\beta} \not\equiv \{m, \bar{m}\} \\
(\nu m)P \downarrow \bar{\beta} &\quad P \equiv Q Q \downarrow \bar{\beta} \\
P \downarrow \bar{\beta}
\end{align*}
\]

Test is a closed process $R$ and a barb $\beta$. The process $R$ is trying to see if the tested process can be made to exhibit barb $\beta$:

\[
P \sqsubseteq Q \text{ for any test } (R, \bar{\beta}), \quad \text{Testing Preorder} \\
(\nu n)P \downarrow \beta \quad \text{then } (Q | R \downarrow \beta) \\
P \sqsubseteq Q \equiv P \sqsubseteq Q \quad \text{Testing Equivalence}
\]

The idea about testing equivalence builds De Nicola and Hennessy [3].

3. **SECURITY PROPERTIES AND VERIFICATION PROCEDURE**

For the verification of cryptographic protocols it is useful first define security properties [4] of these protocols.

**Secrecy**: $M$ is secret if a session that contains $M$ is indistinguishable from any session containing some data $M_0$ in place of $M$ (observational equivalence property). Global secrecy is when a message is secret all the time. Local secrecy is when a message is secret till the corresponding session has not ended.

**Authenticity**: If $A$ accepts a message $M$ as coming from $B$ then $B$ actually sent $M$. If $A$ received a message of form $M_1$ then $B$ sent a message of form $M_2$. If $A$ got a message of form $M$ then $B$ was active. If $A$ has got a message $M$ $n$ times then $B$ sent it $n$ times.

In this project we want to proceed verification of cryptographic protocols by means of validation of the secrecy and the authenticity. We define the safety property.

**Definition 4.1**: Safety

- **Authenticity**: $B$ always replies $F$ to the message $M$ that $A$ sends; an attacker can’t cause $B$ to apply $F$ to some other message.
- **Secrecy**: The message $M$ can’t be read in transit from $A$ to $B$; if $F$ doesn’t reveal $M$, then the whole protocol doesn’t reveal $M$.

Protocol is safe only if both conditions, authenticity and secrecy, are satisfied. In summary, we have:

\[
\begin{align*}
\text{Inst}(M) &\equiv \text{Inst}_{spec}(M), \text{ for all } M \quad \text{Authenticity} \\
\text{Inst}(M) &\equiv \text{Inst}(M'), \text{ if } F(M) \simeq F(M'), \text{ for all } M, M'
\end{align*}
\]

3.1. **Verification Procedure**

We designed following procedure to verify the safety properties of the communication protocols:

1. Write the protocol into convenient form. The best is writing it with messages.
2. Make the spi-calculus description of this protocol.
3. Make specification from description of this protocol.
4. Verify authenticity:
   - Make specification for authenticity.
   - Verify authenticity by exhibiting auxiliary equivalences (strong bisimilarity, barbed equivalence, and barbed congruence).
5. Verify secrecy:
   - Prove restricted version of secrecy property \( \text{Inst}(M) \simeq \text{Inst}(M') \) if \( F(x) \) is \( \tilde{c}(\cdot) \).
   - Prove full secrecy property \( \text{Inst}(M) \simeq \text{Inst}(M') \) if \( F(M) \simeq F(M') \) using auxiliary equivalences.

6. If both authenticity and secrecy are valid, then the protocol is secure.

4. EXAMPLES

Two principals \( A \) and \( B \) share the key \( K_{AB} \), we assume there is a public channel \( c_{AB} \) that \( A \) and \( B \) use for communication. The protocol is simply that \( A \) sends a message \( M \) under \( K_{AB} \) to \( B \), on \( c_{AB} \).

To verify the safety properties of the protocol we use the above procedure.

1. Message 1 \( A \rightarrow B : \{ M \}_{K_{AB}} \) on \( c_{AB} \)

2. Specification in spi-calculus
   \[
   \begin{align*}
   A(M) &= c_{AB}(M)_{K_{AB}} \\
   B_{\text{spec}} &= c_{AB}(x).\text{case } x \text{ of } \{ y \}_{K_{AB}} \text{ in } F(y) \\
   \text{Inst}_{\text{spec}}(M) &= (vK_{AB})(A(M) | B_{\text{spec}}(M))
   \end{align*}
   \]

3. The main definitions are:
   \[
   \begin{align*}
   \text{Inst}(M) &= (vc_{AB})(\text{spec}(M)).0 | c_{AB}(x).F(x) \\
   \text{Inst}_{\text{spec}}(M) &= (vc_{AB})(\text{spec}(M)).0 | c_{AB}(x).F(M))
   \end{align*}
   \]

4. Proposition 5.1: For any closed term \( M \), \( \text{Inst}(M) \simeq \text{Inst}_{\text{spec}}(M) \).
   Only commitments of \( \text{Inst}(M) \) and \( \text{Inst}_{\text{spec}}(M) \) are:
   \[
   \begin{align*}
   \text{Inst}(M) & \xrightarrow{\tau} (vc_{AB})(0 | F(M)) \\
   \text{Inst}_{\text{spec}}(M) & \xrightarrow{\tau} (vc_{AB})(0 | F(M))
   \end{align*}
   \]
   From definition of barbed congruence we know, that strong bisimilarity implies barbed congruence and barbed congruence implies testing equivalence.
   \[
   \begin{align*}
   \text{Inst}(M) & \sim \text{Inst}_{\text{spec}}(M) \\
   \text{Inst}(M) & \sim \text{Inst}_{\text{spec}}(M) \\
   \text{Inst}(M) & \simeq \text{Inst}_{\text{spec}}(M)
   \end{align*}
   \]

5. First we prove restricted version of secrecy property. \textbf{Lemma 5.2}: \( \text{Inst}(M) \simeq \text{Inst}(M') \) if \( F(M') \) is \( \tilde{\tau}(\cdot) \), for any closed terms \( M \) and \( M' \). Only commitment of \( \text{Inst}(N) \) is: \( \text{Inst}(N) \xrightarrow{\tau} (vc_{AB})(0 | \tilde{\tau}(\cdot)) \) and so clearly \( \text{Inst}(M) \sim \text{Inst}(M') \). Like in previous, \( \text{Inst}(M) \simeq \text{Inst}(M') \). Now we can make calculation of full secrecy property, \( \text{Inst}(M) \simeq \text{Inst}(M') \) if \( F(M) \simeq F(M') \). In special case, where \( F(x) \) is \( \tilde{\tau}(\cdot) \) we can write \( \text{Inst}(M), (x)\tilde{\tau}(\cdot) \). We assume that \( c \) is a fresh name and \( y \) fresh variable and we write \( \tau.F(N) \) for \( (vc)(\tilde{\tau}(\cdot) | c(y).F(N)) \). Only commitments are:
   \[
   \begin{align*}
   (vc)(c_{AB}(x).\tilde{\tau}(\cdot) | c(y).F(N)) & \xrightarrow{c_{AB}(x).\tau} (c_{AB}(x).F(N)) \\
   (vc)(c_{AB}(x).\tilde{\tau}(\cdot) | c(y).F(N)) & \xrightarrow{c_{AB}(x).\tau} (c_{AB}(x).F(N))
   \end{align*}
   \]
   From these, we have: \( (vc)(c_{AB}(x).\tilde{\tau}(\cdot) | c(y).F(N)) \sim (c_{AB}(x).F(N)) \).
   As follows using proposition \( F(N) \simeq \tau.F(N) \), facts that testing equivalence is congruence and that strong bisimilarity implies testing equivalence, we have:
   \[
   \begin{align*}
   \text{Inst}_{\text{spec}}(N) &= (vc_{AB})(\text{spec}(N)).0 | c_{AB}(x).F(N) \\
   &\simeq (vc_{AB})(\text{spec}(N)).0 | c_{AB}(x).F(N)) \\
   &\simeq (vc_{AB})(\text{spec}(N)).0 | (vc)(c_{AB}(x).\tilde{\tau}(\cdot) | c(y).F(N)) \\
   &\equiv (vc)(\text{spec}(N)).0 | (vc)(c_{AB}(x).\tilde{\tau}(\cdot) | c(y).F(N)) \\
   &\equiv (vc)(\text{spec}(N)).0 | (vc)(c_{AB}(x).\tilde{\tau}(\cdot) | c(y).F(N)) \\
   &= (vc)(\text{spec}(N)).0 | (vc)(c(y).F(N))
   \end{align*}
   \]
   And we obtain equation: \( \text{Inst}_{\text{spec}}(N) \simeq (vc)(\text{spec}(N)).0 | (vc)(c(y).F(N)) \). With this equation, Lemma 5.2, Proposition 5.1 and assumption \( F(M) \simeq F(M') \) we can make following calculation.
   \[
   \begin{align*}
   \text{Inst}(M) & \simeq \text{Inst}_{\text{spec}}(M) \\
   &\simeq (vc)(\text{spec}(M)).0 | (vc)(c(y).F(M)) \\
   &\simeq (vc)(\text{spec}(M')).0 | (vc)(c(y).F(M')) \\
   &\simeq \text{Inst}_{\text{spec}}(M') \\
   &\simeq \text{Inst}(M')
   \end{align*}
   \]

6. Authenticity and secrecy property are valid, protocol is secure.

5. CONCLUSIONS

This work describes verification of cryptography protocols with emphasis on authenticity and secrecy properties using spi-calculus. The main task was to design a common procedure of the verification, which can be applied on any cryptographic protocol. Presented results are based on Abadi’s and Gordon’s testing equivalence and auxiliary equivalences [3]. This approach is more suitable for automation than solution designed by Woo and Lam [2]. Future extension of this work may be a software implementation of designed procedure.
